BEM IN PERFORMANCE OF NOISE BARRIERS

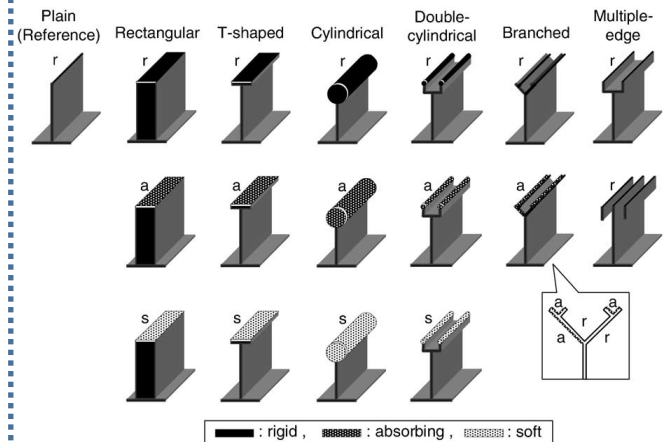

OKUBO & FUJIWARA (1998)

- Efficiency of a noise barrier on the ground with an acoustically soft cylindrical edge. *Journal of Sound and Vibrations* **216(5)**, 771-790.

ISHIZUKA & FUJIWARA (2004)

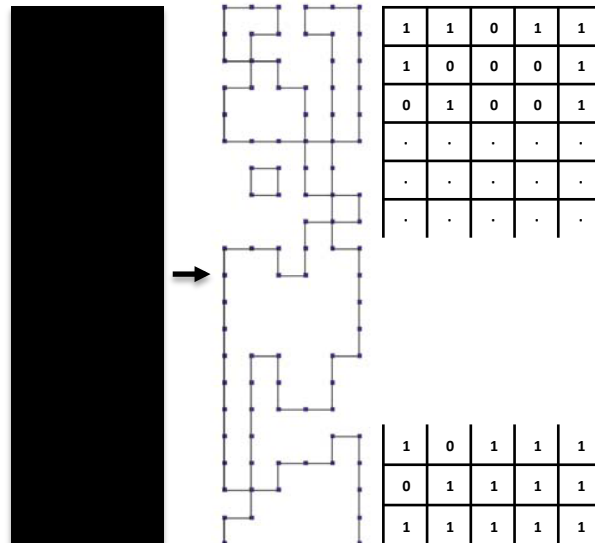

- Performance of noise barriers with various edge shapes and acoustical conditions. *Applied Acoustics* **65**, 125-141.

GA AND BEM IN SHAPE OPTIMIZATION

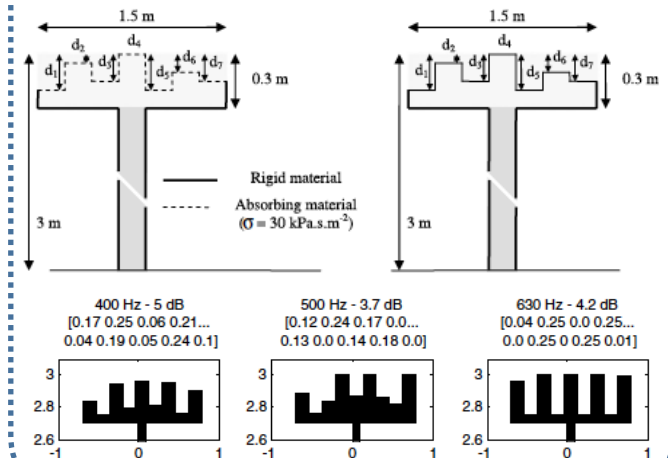

DUHAMEL (2006)

- Shape optimization of noise barriers using genetic algorithms. *Journal of Sound and Vibrations* **297**, 432-443.

BAULAC ET AL. (2008)

- Optimisation with genetic algorithm of the acoustic performance of T-shaped noise barriers with a reactive top surface. *Applied Acoustics* **69**, 332-342.

GA AND BEM IN SHAPE OPTIMIZATION

GREINER ET AL. (2010)

- Single- and multi-objective shape design of Y-noise barriers using evolutionary computation and boundary elements. *Advances in Engineering Software* **41**, 368-378.

OVERVIEW

- Both a single- and a multi-objective Y-shaped design optimization is carried out.
- Single-objective problem: to fit the Y-IL graph to a given reference one (inverse problem).
- Multi-objective problem: to both fit the Y-IL graph to the given reference and minimize the overall length of the barrier boundary intended to be optimized

ACOUSTIC EFFICIENCY OF THE BARRIER

INSERTION LOSS COEFFICIENT (IL)

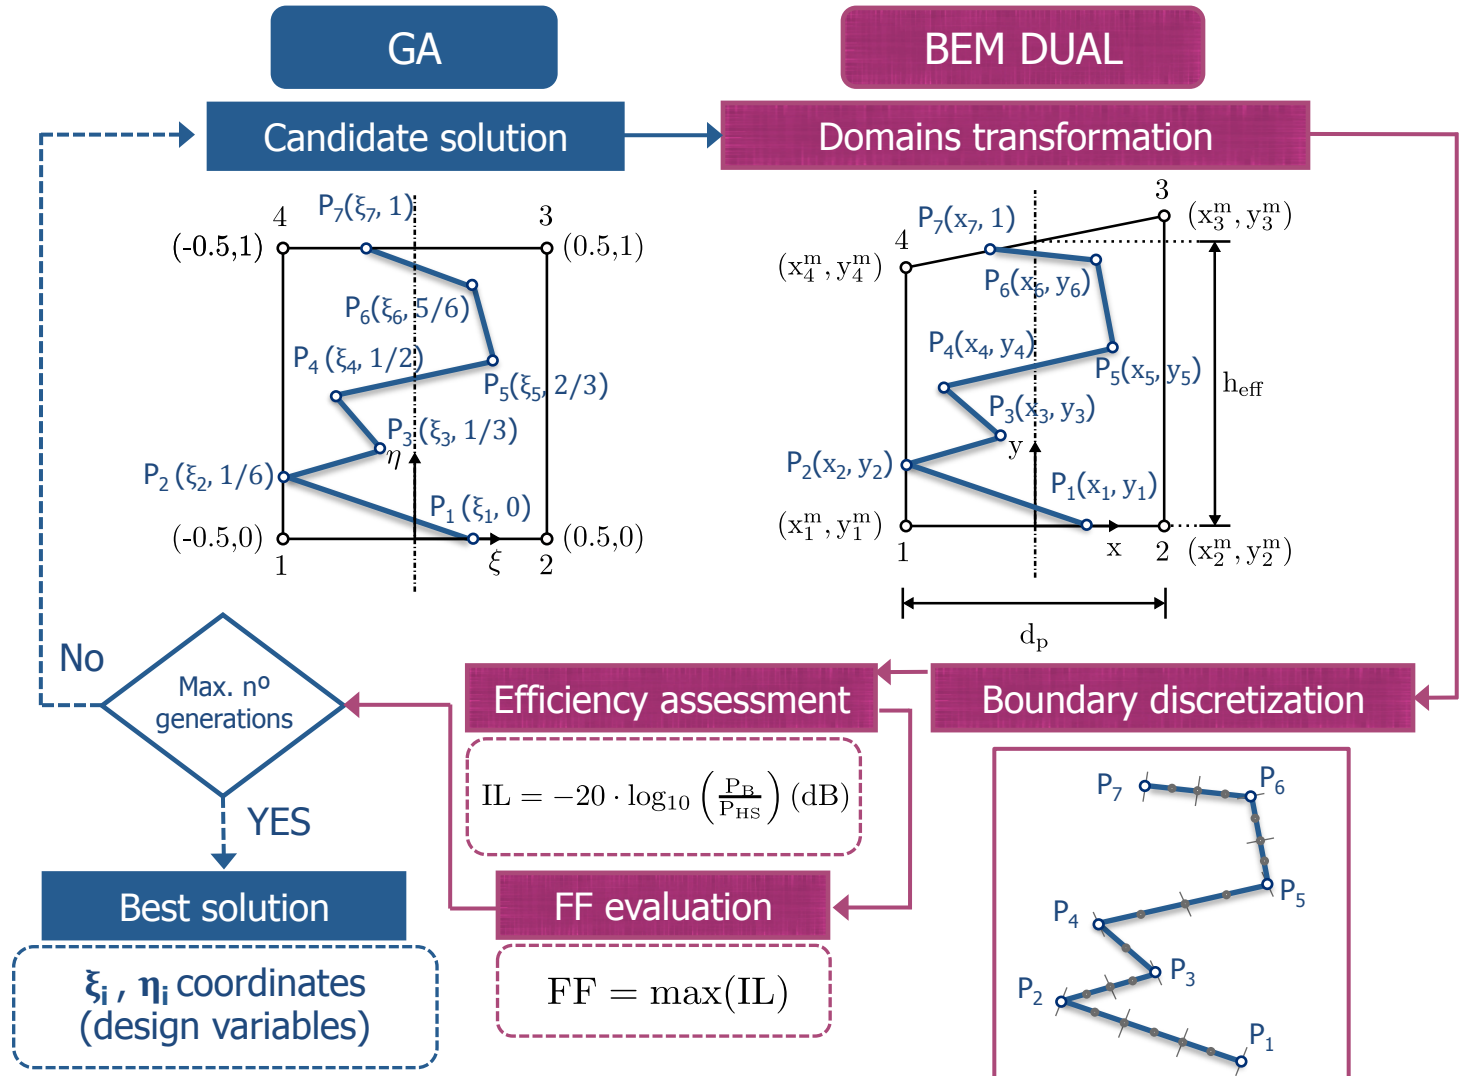

- Difference in acoustic pressure levels before and after the inclusion of the barrier.
- Measured in decibels (dB).
- Broadly used in the evaluation of noise control measures.
- Expression:

$$IL = -20 \cdot \log_{10} \left(\frac{P_B}{P_{HS}} \right) \text{ (dB)}$$

EFICIENCY ASSESSMENT

- IL values collected for certain points of the domain (receivers):

IL ASSESSMENT THROUGH OPTIMIZATION

DEALING WITH LARGE GEOMETRIES

OUTDOOR ACOUSTIC PROBLEM

INDOOR ACOUSTIC PROBLEM

PROBLEMS RELATED

- Spurious frequencies (eigenfrequencies) related to the indoor acoustic problem arise.
- The acoustic efficiency of the barrier is seriously affected.

DEALING WITH THIN-CROSS SECTION CONF.

REAL VOLUMETRIC THIN BARRIER

IDEALIZED NULL-THICKNESS BARRIER

PROBLEMS RELATED

- Numerical integration problems may arise for volumetric thin barriers.
- The acoustic efficiency of the barrier is affected.

Boundary Elements Method (BEM)

DUAL FORMULATION. NULL-THICKNESS BOUNDARIES

SINGULAR FORMULATION

$$\frac{1}{2} \cdot \Sigma \mathbf{p}_i + \sum_{j=1}^{NE} \mathbf{H}_j^+ \cdot \Delta \mathbf{p}_j = \sum_{j=1}^{NE} \mathbf{G}_j^+ \cdot \Sigma \mathbf{q}_j + \mathbf{p}_0^*$$

HYPER-SINGULAR FORMULATION

$$\frac{1}{2} \cdot \Delta \mathbf{q}_i + \sum_{j=1}^{NE} \mathbf{M}_j^+ \cdot \Delta \mathbf{p}_j = \sum_{j=1}^{NE} \mathbf{L}_j^+ \cdot \Sigma \mathbf{q}_j + \frac{\partial \mathbf{p}_0^*}{\partial \mathbf{n}_i}$$

RESULTING SYSTEM OF EQUATIONS

$$\begin{bmatrix} \frac{\mathbf{I}}{2} - \mathbf{G}^+ \mathbf{A}^+ & \mathbf{H}^+ - \mathbf{G}^+ \mathbf{A}^- \\ \frac{\mathbf{A}^-}{2} \mathbf{I} - \mathbf{L}^+ \mathbf{A}^+ & \frac{\mathbf{A}^+}{2} \mathbf{I} + \mathbf{M}^+ - \mathbf{L}^+ - \mathbf{A}^- \end{bmatrix} \begin{bmatrix} \Sigma \mathbf{p} \\ \Delta \mathbf{p} \end{bmatrix} = \begin{bmatrix} \mathbf{p}_0^* \\ \frac{\partial \mathbf{p}_0^*}{\partial \mathbf{n}_i^+} \end{bmatrix}$$

PRESSURE AND FLUX AT BOTH SIDES

- Introduction

- Developments

PROBLEM DEFINITION

- Perfectly reflective both barrier and ground surface ($\beta_s = \beta_p = 0$).
- Feasible region defined by effective height ($h_{\text{eff}} = 3$ m) and horizontal projection on the ground ($d_p = 1$ m).
- Source laid on the ground at $d_s = 10$ m.
- Two receivers configurations: 4 rec. on the ground and 4x4 grid of receivers.

RECEIVERS PLACEMENT

- Three regions in terms of closeness to the barrier are studied:

Region	d_s	d_p	d_{r1}	d_{r2}	Δx	Δy
1			0.5	10	2	1
2	10	1	10.5	40	8	2
3			50.5	50	10	5

Developments

APPLIED SPECTRA

- A-weighted normalized traffic noise spectra of vehicle by CTE (ISO 717.2).
- Study conducted for third octave frequencies ranging 100-2000 Hz.

$$\bar{IL} = -10 \cdot \log_{10} \left(\frac{\sum_{i=1}^{NF} 10^{(A_i - IL_i)/10}}{\sum_{i=1}^{NF} 10^{A_i/10}} \right) \text{ (dBA)}$$

FITNESS FUNCTION (FF)

- Shape optimization based on the IL average at receiver points:

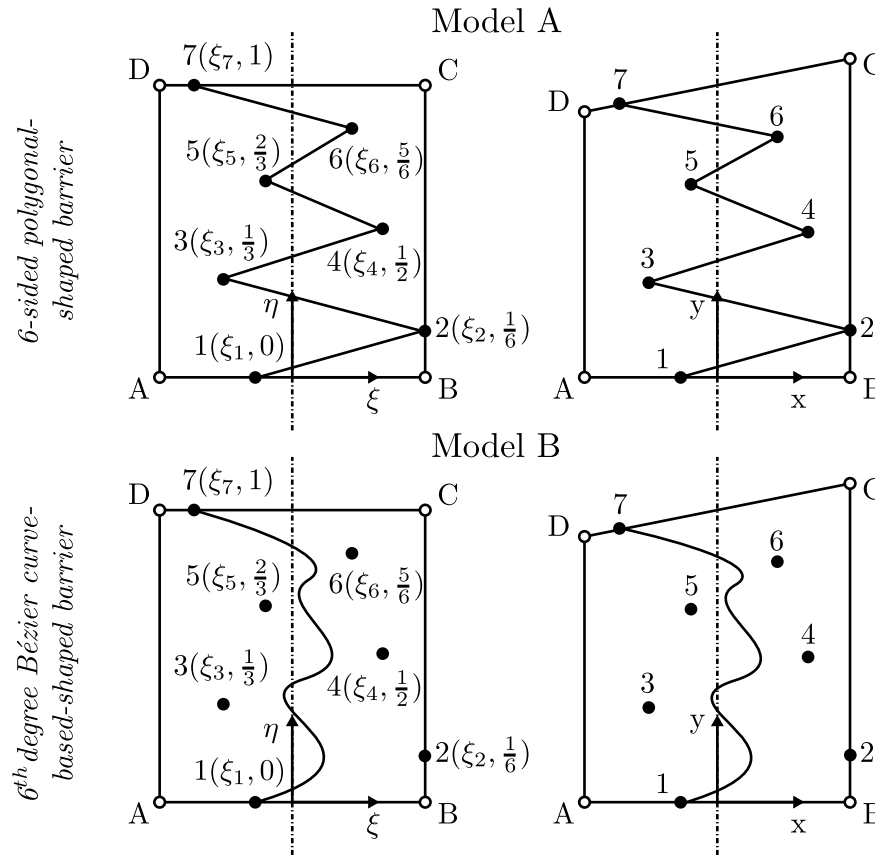

$$FF = \sum_{j=1}^{NR} \bar{IL}_j / NR$$

- The aim is to maximize the FF value (the higher its value the higher the acoustic efficiency of the proposed barrier).

*Receiver configuration.

RESULTS DISCUSSION

MODELS COMPARISON

- The polygonal-shaped barrier (model A) shows a better performance for near regions when receivers are placed on the ground (Ca).
- However, the 6th degree Bézier curve-shaped barrier (model B) performs a better acoustic behaviour for non-near regions (over 1 dBA) .
- Both models display a similar acoustic performance when a grid of receivers is considered.

MODELS VS. STRAIGHT

- Models studied herein clearly outperform the acoustic efficiency of the straight barrier for all regions and receivers configurations.
- The need to study alternatives designs to the vertical screen is suggested, even for far regions.

Developments

- A methodology for the optimization of the performance assessment of complex thin noise barriers designs by idealizing their profiles as null thickness boundaries has been presented.
- Two noise barrier models has been studied to validate the method.
- The range of applications of the procedure is broad and enables the study of diverse topological solutions, including those involving curve geometries.
- Idealizing complex thin-cross section barrier configurations as null boundary thickness-like models strongly ease the topological validation of the individuals proposed by the GA, yielding conclusions difficult to be drawn without the application of this methodology.

HYBRID-BOUNDARIED NOISE BARRIERS

QUADRATIC RESIDUE DIFFUSER (QRD)

- Optimization of configurations with a certain number of wells.
